Lightning review of CFT

- 2d Conformal Field Theory is essentially a collection of maps $(\Sigma, \{V_i(z_i)\}) \rightarrow \mathbb{C}$

obeying certain well motivated and known axioms such as gluing conditions or

$$V_i(z)V_j(w) = \sum_k \frac{C_{ij}^k}{(z-w)^{h_i+h_j-h_k}} V_k(w) + \dots$$

Lightning review of CFT

- Every CFT possesses a special holomorphic operator

$$T(z) = \sum_n \frac{L_n}{z^{n+2}} \quad [L_n, L_m] = \frac{c}{12}n(n^2 - 1)\delta_{n+m} + (n - m)L_{n+m}$$

and its antiholomorphic counterpart

$$\bar{T}(\bar{z}) = \sum_n \frac{\bar{L}_n}{\bar{z}^{n+2}}$$

which obey

$$T(z)V(w, \bar{w}) = \cdots + \frac{h}{(z-w)^2}V(w, \bar{w}) + \frac{1}{z-w}\partial V(w, \bar{w}) + \cdots$$

$$T(z)T(w) = \frac{c}{2(z-w)^4} + \frac{h}{(z-w)^2}T(w) + \frac{1}{z-w}\partial T(w) + \cdots$$

Example of an CFT: Ising model

- One of the simplest systems is the Ising (more properly Lenz-Onsager) model of interacting spins

with Hamiltonian

$$\mathcal{H}(\{\sigma_i\}) = -J \sum_{(i,j)} \sigma_i \sigma_j - B \sum_i \sigma_i,$$

Example of an CFT: Ising model

- This model is described by the partition sum

$$Z = \sum_{\{\sigma\}} e^{-\frac{H(\{\sigma\})}{kT}}$$

and shows very different behavior depending on the temperature

- a) high temperature phase
- b) critical temperature
- c), d) low temperature phases

Example of an CFT: Ising model

- At **critical** temperature it becomes the simplest 2D CFT with $c = \frac{1}{2}$ (free Majorana fermion)

- Magnetization and energy are described by local operators σ and ϵ with scale dimension $\frac{1}{16}$ and $\frac{1}{2}$. For instance 2-point functions of magnetization or energy density can be obtained very simply (critical exponents equal to $-1/4$ and -2).

Example of an CFT: Ising model

- In practice we often need boundary conditions. Which of those preserve the conformal symmetry?

The figure depicts ++, --, free-free and periodic b.c..

Interestingly the number of allowed conformal boundary conditions is the same as the number of local operators in a CFT (as shown by Cardy in 1980's)

In particular: $+ \leftrightarrow 1$,
 $- \leftrightarrow \varepsilon$,
free $\leftrightarrow \sigma$

Defects in CFT

- In the underlining lattice realization **defects** are very simple objects (change of coupling along some bonds)

- Boundary conditions on the defect can be
 - a) fully reflecting (same as pair of b.c.)
 - b) fully transmitting (e.g. trivial defect)
 - c) ...arbitrary

Defects in CFT

There are two special families of defects:

- **Conformal defects** (defects preserving energy in 1-dim picture) $T(z) - \bar{T}(\bar{z})$ is continuous; can be studied by folding trick
- **Topological defects** (preserve energy and momentum); $T(z), \bar{T}(\bar{z})$ are separately continuous, hence everything is invariant under small deformations. They are naturally associated to *homotopy* cycles.

Topological defects: Brief review

- Topological defects give rise to closed string operators obeying

$$[L_n, D] = [\tilde{L}_n, D] = 0, \quad \forall n$$

- For diagonal minimal models they are labeled by the same index as primary fields. By Schur's lemma they are constant on every Verma module

$$D_d = \sum_i X_{di} P^i$$

where P^i are projectors on the i -th Verma module

Topological defects: Brief review

- Bring two topological defects close to each other, the result will be a sum of elementary defects

$$D_d D_c = \sum_{e \in d \times c} D_e = \sum_e N_{dc}^e D_e$$

Defects obey so called **fusion algebra**

Topological defects: Brief review

- For minimal models it is readily verified

$$D_a D_b = \left(\sum_i \frac{S_{ai}}{S_{0i}} P^i \right) \left(\sum_j \frac{S_{bj}}{S_{0j}} P^j \right)$$

$$= \sum_i \frac{S_{ai}}{S_{0i}} \frac{S_{bi}}{S_{0i}} P^i$$

←Verlinde formula used

$$= \sum_i \sum_c N_{ab}^c \frac{S_{ci}}{S_{0i}} P^i$$

$$= \sum_c N_{ab}^c D_c$$

$$[\phi_a] \times [\phi_b] = \sum_c N_{ab}^c [\phi_c]$$

Petkova, Zuber 2000

Defect networks

- Let us consider defects ending on defects

and hence

NB: This looks just like transformation properties of 4pt-conformal blocks.

It can be also justified by the TFT approach of Felder, Fröhlich, Fuchs, Runkel and Schweigert

Defect networks

- Key consistency relation (pentagon identity)

$$\sum_s F_{ps} \begin{bmatrix} b & c \\ a & q \end{bmatrix} F_{qt} \begin{bmatrix} s & d \\ a & e \end{bmatrix} F_{sr} \begin{bmatrix} c & d \\ b & t \end{bmatrix} = F_{qr} \begin{bmatrix} c & d \\ p & e \end{bmatrix} F_{pt} \begin{bmatrix} b & r \\ a & e \end{bmatrix}$$

axiom of monoidal
(tensor) category
or Elliott-Biedenharn
identity for 6j symbols

By Mac Lane coherence theorem guarantees consistency

Defect networks

- Various properties

$$F_{pq} \begin{bmatrix} a & b \\ c & d \end{bmatrix} = 1 \quad \text{whenever } 1 \in \{a, b, c, d\}$$

$$\sum_s F_{ps} \begin{bmatrix} b & c \\ a & d \end{bmatrix} F_{sr} \begin{bmatrix} c & d \\ b & a \end{bmatrix} = \delta_{pr}.$$

- In special cases (parity invariant defect in parity invariant theory) also symmetry under permutation of rows and columns

Defect networks

- In the absence of obstructions one can get rid of defect loops

$$\begin{array}{c}
 \begin{array}{c} a \\ \text{---} \bigcirc \text{---} \\ i \qquad j \\ b \end{array} = \begin{array}{c} a \\ \text{---} \bigcirc \text{---} \\ i \qquad j \\ b \\ \text{---} \end{array} = \sum_k F_{1k} \begin{bmatrix} a & b \\ a & b \end{bmatrix} \begin{array}{c} a \qquad a \\ \text{---} \bigcirc \text{---} \text{---} \bigcirc \text{---} \\ i \qquad k \qquad j \\ b \qquad b \end{array} \\
 \\
 \Downarrow \\
 \begin{array}{c} a \\ \text{---} \bigcirc \text{---} \\ i \qquad j \\ b \end{array} = \frac{\delta_{ij}}{F_{1i} \begin{bmatrix} a & b \\ a & b \end{bmatrix}} \text{---} i \text{---} i
 \end{array}$$

Defect networks

- From that the sunset diagram follows

$$\begin{array}{c} a \\ \circlearrowleft \\ c \\ \hline \\ b \end{array} = \frac{1}{F_{11} \begin{bmatrix} a & a \\ a & a \end{bmatrix} F_{1a} \begin{bmatrix} b & c \\ b & c \end{bmatrix}} = \Delta(a, b, c)$$

- Another curious relation (part of Verlinde formula):

$$\begin{array}{c} a \\ \circlearrowleft \\ \text{---} \\ \mathbb{1} \\ \text{---} \\ \circlearrowleft \\ b \end{array} = \sum_{c \in a \times b} F_{1c} \begin{bmatrix} a & b \\ a & b \end{bmatrix} \begin{array}{c} a \\ \circlearrowleft \\ c \\ \circlearrowleft \\ b \end{array} = \sum_{c \in a \times b} \begin{array}{c} c \\ \circlearrowleft \end{array}$$

↓

Ring of quantum dimensions

$$\frac{1}{F_{11} \begin{bmatrix} a & a \\ a & a \end{bmatrix}} \times \frac{1}{F_{11} \begin{bmatrix} b & b \\ b & b \end{bmatrix}} = \sum_c N_{ab}^c \frac{1}{F_{11} \begin{bmatrix} c & c \\ c & c \end{bmatrix}} \quad g'_a g'_b = \sum_c N_{ab}^c g'_c$$

Defect networks

- An important relation is

$$\begin{array}{c} k \\ | \\ \triangle \\ / \quad \backslash \\ i \quad \quad j \\ c \end{array} = F_{ck} \begin{bmatrix} b & a \\ i & j \end{bmatrix} \times \left(F_{1k} \begin{bmatrix} a & b \\ a & b \end{bmatrix} \right)^{-1} \begin{array}{c} k \\ | \\ \text{Y} \\ / \quad \backslash \\ i \quad \quad j \end{array}$$

which is actually S_3 symmetric (in the parity symmetric case), thanks to nontrivial relations for the fusion matrices.

- This prefactor is 1 when one of the internal line is the identity defect. When one of the external defects is 1, we get simple, but nontrivial normalization for the bubble.

Defect networks

- Another relation of this sort are the tetrahedral identities for the “6j-symbol”

$$\begin{bmatrix} c, a, b \\ k, i, j \end{bmatrix} = \frac{F_{ck} \begin{bmatrix} b & a \\ i & j \end{bmatrix}}{F_{1k} \begin{bmatrix} a & b \\ a & b \end{bmatrix} F_{1i} \begin{bmatrix} j & k \\ j & k \end{bmatrix} F_{11} \begin{bmatrix} i & i \\ i & i \end{bmatrix}}$$

which one gets from defect tetrahedron

Defect action on boundary states

- Action on Cardy boundary states is straightforward

$$\begin{aligned} D_a ||B_b\rangle\rangle &= \sum_i \frac{S_{ai}}{S_{0i}} P^i \left(\sum_j \frac{S_{bj}}{\sqrt{S_{0j}}} |j\rangle\rangle \right) \\ &= \sum_i \frac{S_{ai}}{S_{0i}} \frac{S_{bi}}{\sqrt{S_{0i}}} |i\rangle\rangle && \leftarrow \text{Verlinde formula used} \\ &= \sum_i \sum_c N_{ab}^c \frac{S_{ci}}{\sqrt{S_{0i}}} |i\rangle\rangle \\ &= \sum_c N_{ab}^c ||B_c\rangle\rangle \end{aligned}$$

Graham, Watts 2003

Topological defects in OSFT

- Let us try to define defect action on boundary fields

$$\begin{aligned} D^d : \mathcal{H}_{\text{closed}} &\rightarrow \mathcal{H}_{\text{closed}} \\ \mathcal{D}^d : \mathcal{H}^{(ab)} &\rightarrow \bigoplus_{\substack{a' \in d \times a \\ b' \in d \times b}} \mathcal{H}^{(a'b')} \end{aligned}$$

- Since the defect is topological and we demand $[Q, \mathcal{D}] = 0$ we expect that $[L_n, \mathcal{D}] = 0$ and hence by Schur's lemma

$$\mathcal{D}^d \psi_i^{(ab)} = \sum_{\substack{a' \in d \times a \\ b' \in d \times b}} X_{ia'b'}^{dab} \psi_i^{(a'b')}$$

Topological defects in OSFT

- To satisfy constraint $\mathcal{D}(\phi * \chi) = (\mathcal{D}\phi) * (\mathcal{D}\chi) \quad \forall \phi, \chi$
it is enough to require for primary fields

$$\mathcal{D}^d \left(\phi_i^{(ab)}(x) \phi_j^{(bc)}(y) \right) = \left(\mathcal{D}^d \phi_i^{(ab)}(x) \right) \left(\mathcal{D}^d \phi_j^{(bc)}(y) \right)$$

from which it follows

$$X_{ka'c'}^{dac} C_{ij}^{(abc)k} = \sum_{b' \in d \times b} C_{ij}^{(a'b'c')k} X_{ka'b'}^{dab} X_{kb'c'}^{dbc}$$

For minimal models Runkel found the boundary structure constants

$$C_{ij}^{(abc)k} = F_{bk} \begin{bmatrix} a & c \\ i & j \end{bmatrix} \quad (\text{for the A-series})$$

Topological defects in OSFT

- Inserting this explicit solution into the constraint we found a general solution

$$X_{ia'b'}^{dab} = \frac{N(d, a, a')}{N(d, b, b')} F_{b'a} \begin{bmatrix} i & b \\ a' & d \end{bmatrix}$$

Generalizes result by Graham and Watts (2003)

thanks to the *pentagon identity* of rational CFT.

- Further demanding twist symmetry fixes the form

$$X_{ia'b'}^{dab} = F_{di} \begin{bmatrix} a & b \\ a' & b' \end{bmatrix} \frac{\sqrt{F_{1a'} \begin{bmatrix} a & d \\ a & d \end{bmatrix} F_{1b'} \begin{bmatrix} b & d \\ b & d \end{bmatrix}}{F_{1i} \begin{bmatrix} a & b \\ a & b \end{bmatrix}}$$

Topological defects in OSFT

- Distributivity

$$\mathcal{D}^d \left(\phi_i^{(ab)}(x) \phi_j^{(bc)}(y) \right) = \left(\mathcal{D}^d \phi_i^{(ab)}(x) \right) \left(\mathcal{D}^d \phi_j^{(bc)}(y) \right)$$

can be nicely understood graphically:

$$\begin{aligned}
 & \text{Diagram 1: } \text{Arc } d \text{ from } a \text{ to } c \text{ on line } a' \dots \phi_i \dots b \dots \phi_j \dots c' \text{ with vertical dashed line } 1 \text{ at } b \\
 & = \sum_{b \in d \times b} F_{1b'} \begin{bmatrix} d & b \\ d & b \end{bmatrix} \text{Diagram 2: } \text{Two arcs } d \text{ from } a \text{ to } b \text{ and } b \text{ to } c \\
 & = \sum_{b \in d \times b} \text{Diagram 3: } \text{Two arcs } d \text{ from } a \text{ to } b \text{ and } b \text{ to } c \text{ with } \phi_i \text{ and } \phi_j \text{ in between}
 \end{aligned}$$

Topological defects in OSFT

- Interestingly it turns out that

$$\mathcal{D}^d \mathcal{D}^c \neq \bigoplus_e N_{dc}^e \mathcal{D}_e$$

but fortunately at least

$$\mathcal{D}^d \mathcal{D}^c = U \left(\bigoplus_e N_{dc}^e \mathcal{D}_e \right) U^{-1}$$

is true! The matrices U are simply given by the fusion matrix (Racah symbols), they square to 1, but most importantly they do not contribute to bulk observables.

Topological defects in OSFT

- To understand these extra factors it is convenient to develop a geometric formalism. Moving topological defect towards boundary, we get new boundary conditions. When we want to understand the action on boundary operators we need to fuse it only partway:

$$\mathcal{D}^d \begin{array}{c} \text{---} \\ \begin{array}{ccccc} & a & \bullet & b & \\ & & \phi_i & & \end{array} \end{array} = \sum_{\substack{a' \in d \times a \\ b' \in d \times b}} \begin{array}{c} \begin{array}{c} \text{---} \\ \begin{array}{ccccc} & a' & \text{---} & \bullet & \text{---} \\ & & a & \phi_i & b & \\ & & & & & b' \end{array} \end{array} \end{array}$$

- We have to understand the CFT with defects ending on boundaries and possible operator insertions at junctions

Topological defects in OSFT

- Let us assume that the original boundary conditions a and b arise from the action of defect on the identity boundary condition (if it exists). Then one can reinterpret the same diagram

$$\mathcal{D}^d \quad \text{---} \underset{a}{\quad} \overset{\phi_i}{\bullet} \quad \text{---} \underset{b}{\quad} \quad = \quad \sum_{\substack{a' \in d \times a \\ b' \in d \times b}} \text{---} \underset{a'}{\quad} \overset{d}{\text{---}} \underset{a}{\quad} \overset{\phi_i}{\bullet} \underset{b}{\quad} \text{---} \underset{b'}{\quad}$$

as one for *defect action* on *defect changing operators*

Topological defects in OSFT

- So finally the extra factors in

$$\mathcal{D}^d \mathcal{D}^c = U \left(\bigoplus_e N_{dc}^e \mathcal{D}^e \right) U^{-1}$$

can be deduced for example from

The diagrammatic equation shows the decomposition of a product of two defects into a sum over a third defect. On the left, a horizontal line represents a worldsheet with points a'' , a' , a , ϕ_i , b , b' , and b'' marked. A smaller semi-circular arc labeled c is centered at ϕ_i and spans from a' to b' . A larger semi-circular arc labeled d is also centered at ϕ_i and spans from a'' to b'' . A vertical dashed line connects the top of arc c to the top of arc d . This is equal to a sum over $e \in d \times c$ of $F_{1e} \begin{bmatrix} c & d \\ c & d \end{bmatrix}$ multiplied by a diagram on the right. The right diagram shows the same horizontal line and points, but with a single semi-circular arc labeled e centered at ϕ_i and spanning from a' to b' .

or better yet by refusing on a' and b' defect

Summary

- Topological defects are a fundamental ingredient in 2d CFTs and they lead to a lot of exciting mathematics
- The topological defects can also be used to relate different solutions in various theories, but one has to be careful when extending their action on open string fields
