

Kontsevich integral for a non-even associator and cabling

Ján Pulmann

University of Geneva

Joint work with Pavol Ševera

Kontsevich integral

Invariant of:

knots

links

braids

tangles

valued in the vector space of *chord diagrams*. Chord is a pair of points on a 1-dim manifold, the *support*.

\implies support is a disjoint union of oriented circles S^1 and intervals I .

Chord diagrams

$\mathcal{P}(X)$ contains linear combination of *chord diagrams on X* :

- chord connects two points on X
- for n chords, all $2n$ points are distinct
- graded by the number of chords
- quotient by diffeomorphisms and the 4-term relation:

For X an interval: $\mathcal{P}(I) = \mathbb{R} \langle \uparrow, \uparrow \circlearrowleft, \uparrow \circlearrowright, \uparrow \circlearrowright = \uparrow \circlearrowleft, \dots \rangle$

How to compute $\hat{Z}(T)$

à la Le, Murakami

Main ingredient is the **Drinfeld associator** Φ : element of free associative algebra $\mathbb{C}\langle\langle X, Y \rangle\rangle$ satisfying some consistency equations.

$$\Phi(X, Y) = 1 + \frac{1}{24}(XY - YX) + \dots$$

Unnormalized Kontsevich integral Z :

-  \mapsto  + $\frac{1}{2}$  + $\frac{1}{2^2} \cdot \frac{1}{2!}$  + ... = $\exp \frac{t-1}{2}$
-  \mapsto Φ $\left(\begin{array}{c} \uparrow \uparrow \\ \downarrow \end{array}, \begin{array}{c} \uparrow \\ \uparrow \uparrow \end{array} \right) =$
 $= \uparrow \uparrow \uparrow + \frac{1}{24} \left(\begin{array}{c} \uparrow \uparrow \uparrow \\ \uparrow \end{array} - \begin{array}{c} \uparrow \uparrow \uparrow \\ \uparrow \end{array} \right) + \dots$
- No normalization:  \mapsto 

Normalization of \cap, \cup

Why normalize?

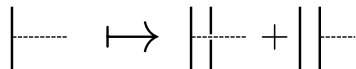

$$\begin{aligned}
 Z(\downarrow \leftarrow \uparrow) &= \text{cup} + \frac{1}{24} (\text{cup} - \text{cup}) + \dots \\
 &= \downarrow + \frac{1}{24} (\text{cup} - \text{cup}) + \dots \equiv \nu^{-1}
 \end{aligned}$$

Normalized \hat{Z} is defined as before, but

$$\begin{aligned}
 \text{cup} &\mapsto \text{cup} \nu^{1/2} \\
 \text{cup} &\mapsto \text{cup} \nu^{1/2}
 \end{aligned}
 \quad \text{which implies} \quad \hat{Z}(\downarrow \leftarrow \uparrow) = \downarrow$$

Last thing we need: \hat{Z} ()

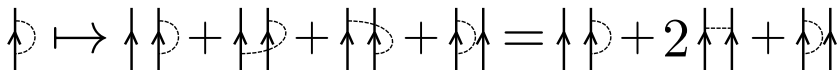

On a doubled component, use a *Leibniz rule*:

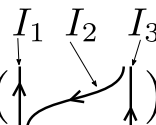

$$\text{---} \mapsto \text{---} + \text{---}$$

For k chord endpoints on a component $C \subset X$, sum over 2^k possible combinations.

This gives a map $\Delta_C : \mathcal{P}(X) \rightarrow \mathcal{P}(X^{(2,C)})$.

For example, $\Delta : \mathcal{P}(I) \rightarrow \mathcal{P}(I \sqcup I)$ acts as

$$\text{---} \mapsto \text{---} + \text{---} + \text{---} + \text{---} = \text{---} + 2 \text{---} + \text{---}$$

At last: \hat{Z} () = $\Delta_{I_2} \Delta_{I_3}^2 \hat{Z}$ ()

Recapitulation

- Z, \hat{Z} is a map: tangles \rightarrow chord diagrams $\mathcal{P}(T)$.
- Defined by values on $\times, \cap, \cup, \swarrow, \searrow$ and then stacked to form a tangle.
- For multiple strands in associator, use $\Delta_C : \mathcal{P}(X) \rightarrow \mathcal{P}(X^{(2,C)})$.

Cabling

We can double components of tangles as well:

Question: Is it true that $\hat{Z}(T^{(2,C)}) = \Delta_C \hat{Z}(T)$

Question: Is it true that $\hat{Z}(T^{(2,C)}) = \Delta_C \hat{Z}(T)$

- For \wr , true by definition
- For \times , true (the *hexagon identity* for the associator)
- Is it true for \cap , i.e. $\hat{Z}(\cap) = \Delta \hat{Z}(\cap) = \Delta \nu^{1/2}$

Theorem (Le & Murakami, 95)

$\hat{Z}(\cap) = \Delta \nu^{1/2} = \hat{Z}(\cup)$ if the associator is even, i.e. if it contains only terms with even numbers of chords $\Phi(X, Y) = \Phi(-X, -Y)$

Thus, $\hat{Z}(T^{(2,C)}) = \Delta_C \hat{Z}(T)$. For knots and links, this is true for any associator, as \hat{Z} does not depend on this associator.

Can we make this work for any associator? (already posed by Le & Murakami)

Cabling for any associator

- For general associator $\hat{Z}(\mathbb{m}) \neq \hat{Z}(\mathbb{u}) \implies$ normalize cap and cup differently
- Let us define $\hat{Z}(\cap) = \alpha$, $\hat{Z}(\cup) = \beta$, both in $\mathcal{P}(I)$
- We still need $\alpha\beta = \nu$: the snake equation $\hat{Z}(\uparrow \curvearrowright \downarrow) = \uparrow$
- The other equation is $\hat{Z}(\mathbb{m}) = \Delta\alpha \iff Z(\mathbb{m}) = (\alpha^{-1} \otimes \alpha^{-1})\Delta\alpha$

$$(\alpha^{-1} \otimes \alpha^{-1})\Delta\alpha = \begin{array}{c} \boxed{\Delta\alpha} \\ \downarrow \quad \downarrow \\ \boxed{\alpha^{-1}} \quad \boxed{\alpha^{-1}} \\ \downarrow \quad \downarrow \end{array}$$

- Similar equation for \mathbb{u} would follow from the previous two.

Proposition (J.P.)

Such α and β do not exist.

Proof by *twisting* of associator Φ .

Associator twists

Let us take (symmetric, invertible) $F \in \mathcal{P}(I \sqcup I)$.

Then, for an associator Φ , define Φ^F as:

This Φ^F is again an associator (satisfies all the necessary equations).

Simple observation: if $F_t = (\alpha^{-1} \otimes \alpha^{-1})\Delta\alpha$, then $\Phi^{F_t} = \Phi$.

(the opposite implication: a theorem by Drinfeld, 1990)

\implies twist Φ by $Z(\mathfrak{m})$.

Recall that we want to find α such that $Z(\mathfrak{m}) = (\alpha^{-1} \otimes \alpha^{-1})\Delta\alpha$

Proposition (J.P.)

The associator $\Phi(X, Y)$ twisted by $Z(\mathfrak{m})$ is equal to

$$\Phi(X, Y)^{Z(\mathfrak{m})} = \Phi(-X, -Y).$$

Thus, if $\Phi(X, Y) \neq \Phi(-X, -Y)$, there exists no α such that $Z(\mathfrak{m}) = (\alpha^{-1} \otimes \alpha^{-1})\Delta\alpha$.

Proof: use the *siphon identity*

Moduli space of flat connections

with Pavol Ševera

Moduli space of flat connections on a surface *with marked points*: gauge transformations are trivial in the points.

Algebra of functions: \mathfrak{g} -quasi-Poisson algebra.

Li-Bland & Ševera, 2013: Quantization of this moduli space: algebra in the category $U\mathfrak{g}\text{-mod}^\Phi$, where $\Phi(X, Y)$ specifies the associative structure.

- minus: algebra in $U\mathfrak{g}\text{-mod}^{\Phi(-X, -Y)}$.
- fusion (as in picture): monoidal functor $U\mathfrak{g}\text{-mod}^{\Phi(X, Y)} \rightarrow U\mathfrak{g}\text{-mod}^{\Phi(-X, -Y)}$.
- monoidal structure given by $Z(\mathfrak{m})$.
